Welcome To ...

Data Structures

王惠嘉

Sorting

- Rearrange n elements into ascending order.
- 7, 3, 6, 2, 1 \rightarrow 1, 2, 3, 6, 7

Insertion Sort

a[0] a[n-2] a[n-1]

- n <= 1 → already sorted. So, assume n > 1.
- a[0:n-2] is sorted recursively.
- a[n-1] is inserted into the sorted a[0:n-2].
- Complexity is O(n²).
- Usually implemented nonrecursively (see text).

Quick Sort

- When $n \le 1$, the list is sorted.
- When n > 1, select a pivot element from out of the n elements.
- Partition the n elements into 3 segments left, middle and right.
- The middle segment contains only the pivot element.
- All elements in the left segment are <= pivot.
- All elements in the right segment are >= pivot.
- Sort left and right segments recursively.
- Answer is sorted left segment, followed by middle segment followed by sorted right segment.

Example

6 2 8 5 11 10 4 1 9 7 3

Use 6 as the pivot.

2 5 4 1 3 6 7 9 10 11 8

Sort left and right segments recursively.

Choice Of Pivot

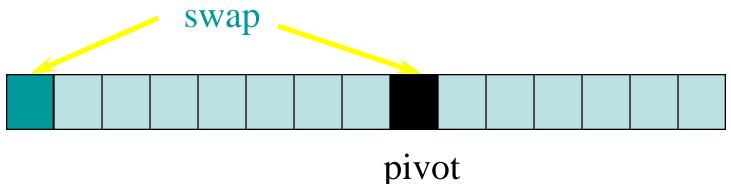

- Pivot is leftmost element in list that is to be sorted.
 - When sorting a[6:20], use a[6] as the pivot.
 - Text implementation does this.
- Randomly select one of the elements to be sorted as the pivot.
 - When sorting a[6:20], generate a random number
 r in the range [6, 20]. Use a[r] as the pivot.

Choice Of Pivot

- Median-of-Three rule. From the leftmost, middle, and rightmost elements of the list to be sorted, select the one with median key as the pivot.
 - When sorting a[6:20], examine a[6], a[13] ((6+20)/2), and a[20]. Select the element with median (i.e., middle) key.
 - If a[6].key = 30, a[13].key = 2, and a[20].key = 10, a[20] becomes the pivot.
 - If a[6].key = 3, a[13].key = 2, and a[20].key = 10,
 a[6] becomes the pivot.

Choice Of Pivot

- If a[6].key = 30, a[13].key = 25, and a[20].key = 10, a[13] becomes the pivot.
- When the pivot is picked at random or when the median-of-three rule is used, we can use the quick sort code of the text provided we first swap the leftmost element and the chosen pivot.

Partitioning Example Using Additional Array

a 6 2 8 5 11 10 4 1 9 7 3

b 2 5 4 1 3 6 7 9 10 11 8

Sort left and right segments recursively.

In-Place Partitioning Example

bigElement is not to left of smallElement, terminate process. Swap pivot and smallElement.

Merge Sort

- Partition the n > 1 elements into two smaller instances.
- First ceil(n/2) elements define one of the smaller instances; remaining floor(n/2) elements define the second smaller instance.
- Each of the two smaller instances is sorted recursively.
- The sorted smaller instances are combined using a process called merge.
- Complexity is O(n log n).
- Usually implemented nonrecursively.

Merge Two Sorted Lists

```
    A = (2, 5, 6)
    B = (1, 3, 8, 9, 10)
    C = ()
```

- Compare smallest elements of A and B and merge smaller into C.
- A = (2, 5, 6) B = (3, 8, 9, 10)C = (1)

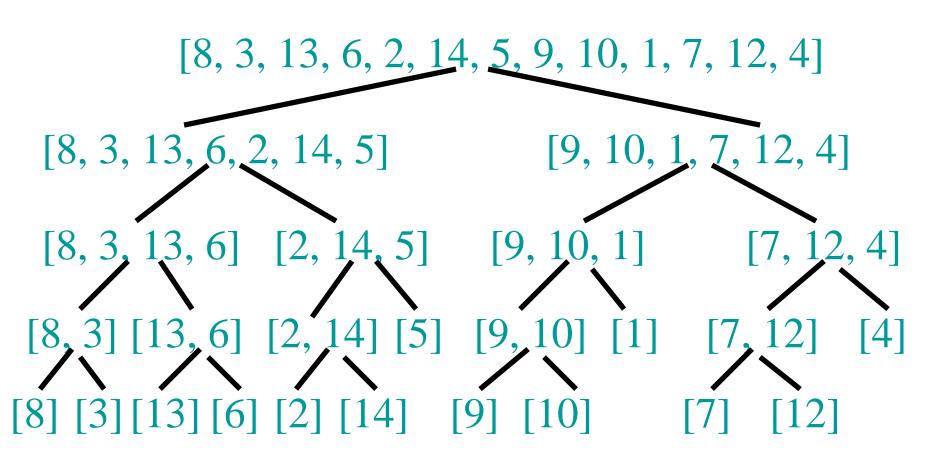

Merge Two Sorted Lists

```
• A = (5, 6)
  B = (3, 8, 9, 10)
  C = (1, 2)
• A = (5, 6)
  B = (8, 9, 10)
  C = (1, 2, 3)
• A = (6)
   B = (8, 9, 10)
  C = (1, 2, 3, 5)
```

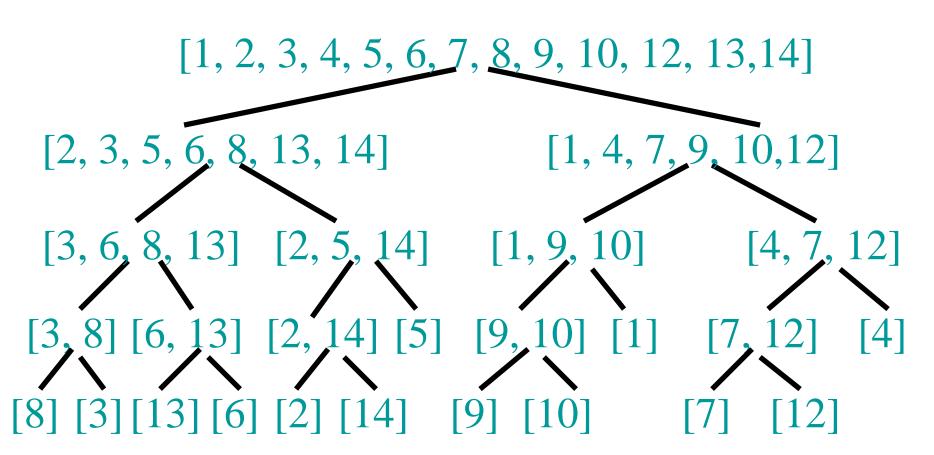

Merge Two Sorted Lists

- A = ()
 B = (8, 9, 10)
 C = (1, 2, 3, 5, 6)
- When one of A and B becomes empty, append the other list to C.
- O(1) time needed to move an element into C.
- Total time is O(n + m), where n and m are, respectively, the number of elements initially in A and B.

Merge Sort

Merge Sort

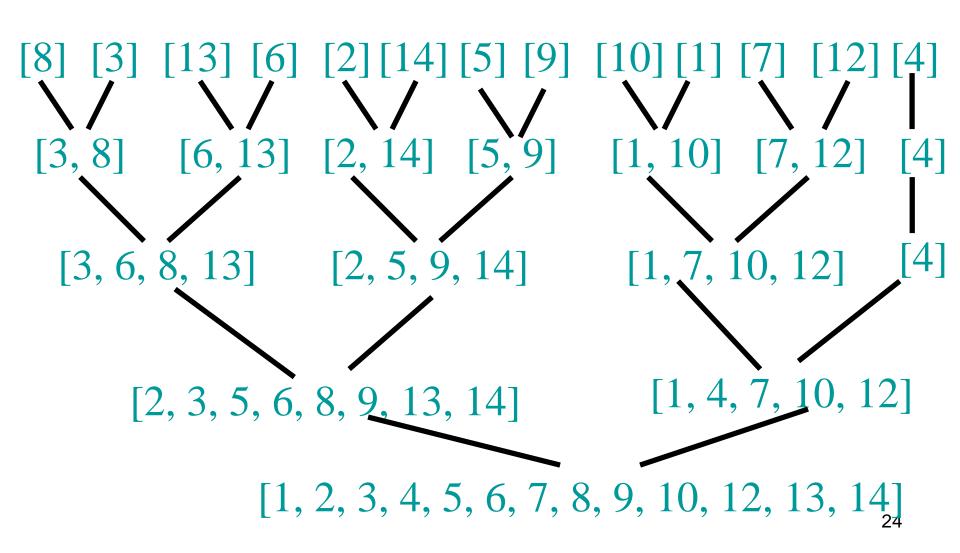

Time Complexity

- Let t(n) be the time required to sort n elements.
- t(0) = t(1) = c, where c is a constant.
- When n > 1,
 t(n) = t(ceil(n/2)) + t(floor(n/2)) + dn,
 where d is a constant.
- To solve the recurrence, assume n is a power of 2 and use repeated substitution.
- $t(n) = O(n \log n)$.

Nonrecursive Version

- Eliminate downward pass.
- Start with sorted lists of size 1 and do pairwise merging of these sorted lists as in the upward pass.

Nonrecursive Merge Sort

Complexity

- Sorted segment size is 1, 2, 4, 8, ...
- Number of merge passes is ceil(log₂n).
- Each merge pass takes O(n) time.
- Total time is O(n log n).
- Need O(n) additional space for the merge.
- Merge sort is slower than insertion sort when n <= 15 (approximately). So define a small instance to be an instance with n <= 15.
- Sort small instances using insertion sort.
- Start with segment size = 15.

Natural Merge Sort

- Initial sorted segments are the naturally ocurring sorted segments in the input.
- Input = [8, 9, 10, 2, 5, 7, 9, 11, 13, 15, 6, 12, 14].
- Initial segments are:

```
[8, 9, 10] [2, 5, 7, 9, 11, 13, 15] [6, 12, 14]
```

- 2 (instead of 4) merge passes suffice.
- Segment boundaries have a[i] > a[i+1].

External Merge Sort

- Sort 10,000 records.
- Enough memory for 500 records.
- Block size is 100 records.
- t_{IO} = time to input/output 1 block (includes seek, latency, and transmission times)
- t_{IS} = time to internally sort 1 memory load
- t_{IM} = time to internally merge 1 block load

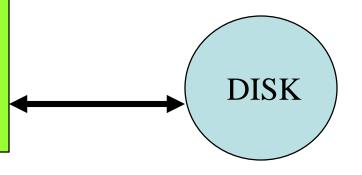

External Merge Sort

- Two phases.
 - Run generation.
 - >A run is a sorted sequence of records.
 - Run merging.

Run Generation

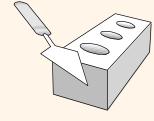

MEMORY
500 records
5 blocks

10,000 records
100 blocks
100 records/ blocks

- Input 5 blocks.
- Sort.
- Output 5 blocks as a run.
- Do 20 times.

- 5t₁₀
- t_{IS}
- 5t₁₀
- $200t_{IO} + 20t_{IS}$

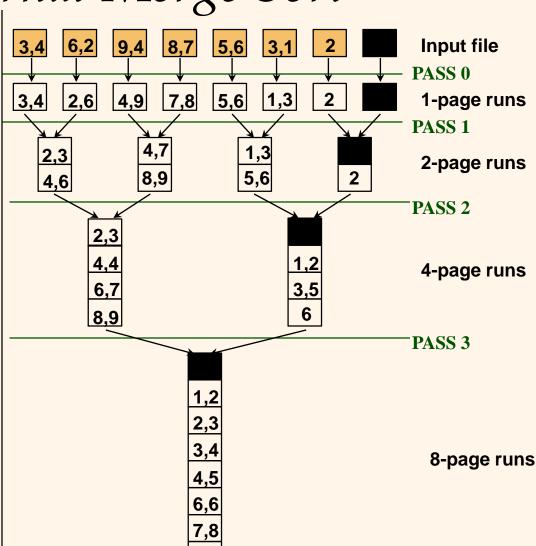

Two-Way External Merge Sort

- Each pass we read + write each page in file.
- * N pages in the file => the number of passes = $\lceil \log_2 N \rceil + 1$
- * So toal cost is:

$$2N(\lceil \log_2 N \rceil + 1)$$

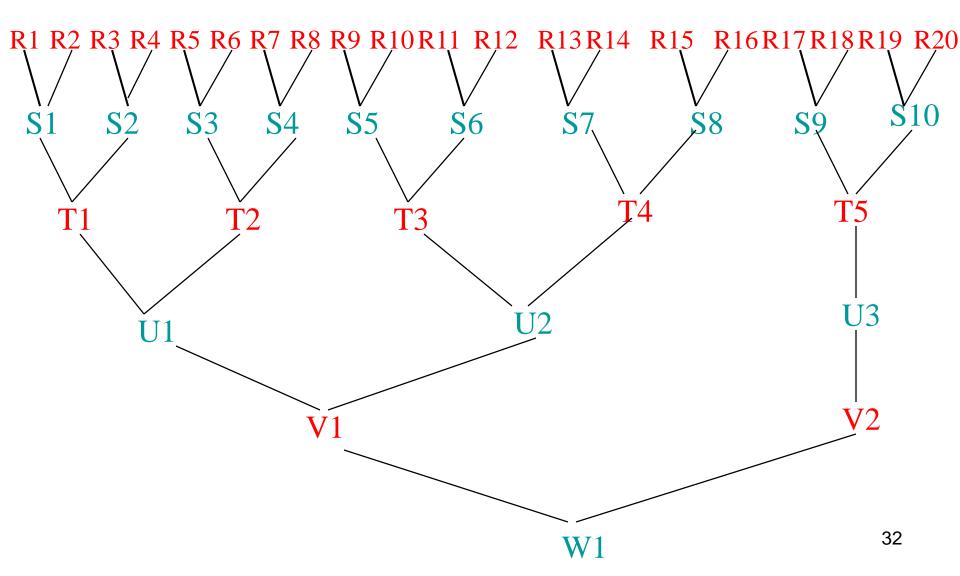

* Idea: Divide and conquer: sort subfiles and merge

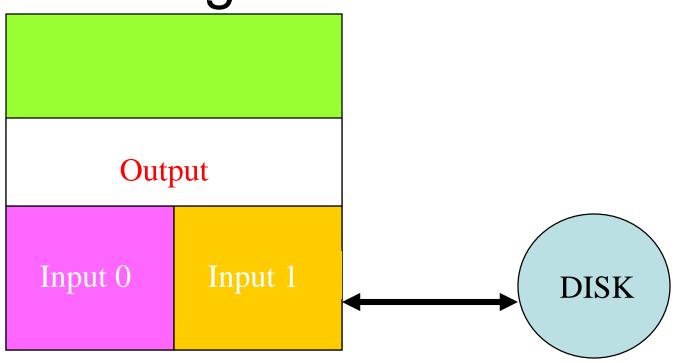

Run Merging

- Merge Pass.
 - Pairwise merge the 20 runs into 10.
 - In a merge pass all runs (except possibly one) are pairwise merged.
- Perform 4 more merge passes, reducing the number of runs to 1.

Merge 20 Runs

Merge R1 and R2

- Fill Io (Input 0) from R1 and I1 from R2.
- Merge from lo and l1 to output buffer.
- Write whenever output buffer full.
- Read whenever input buffer empty.

Time To Merge R1 and R2

- Each is 5 blocks long.
- Input time = $10t_{10}$.
- Write/output time = 10t_{IO}.
- Merge time = $10t_{IM}$.
- Total time = $20t_{IO} + 10t_{IM}$.

Time For Pass 1 (R→S)

- Time to merge one pair of runs
 - $= 20t_{IO} + 10t_{IM}$.
- Time to merge all 10 pairs of runs
 - $= 200t_{IO} + 100t_{IM}$.

Time To Merge S1 and S2

- Each is 10 blocks long.
- Input time = $20t_{10}$.
- Write/output time = 20t_{IO}.
- Merge time = $20t_{IM}$.
- Total time = $40t_{IO} + 20t_{IM}$.

Time For Pass 2 (S→T)

Time to merge one pair of runs

$$= 40t_{IO} + 20t_{IM}$$
.

Time to merge all 5 pairs of runs

$$= 200t_{IO} + 100t_{IM}$$
.

Time For One Merge Pass

- Time to input all blocks = 100t_{IO}.
- Time to output all blocks = 100t_{IO}.
- Time to merge all blocks = 100t_{IM}.
- Total time for a merge pass = $200t_{IO}$ + $100t_{IM}$.

Total Run-Merging Time

 (time for one merge pass) * (number of passes)

```
= (time for one merge pass)

* ceil(log<sub>2</sub>(number of initial runs))

= (200t_{IO} + 100t_{IM}) * ceil(log<sub>2</sub>(20))

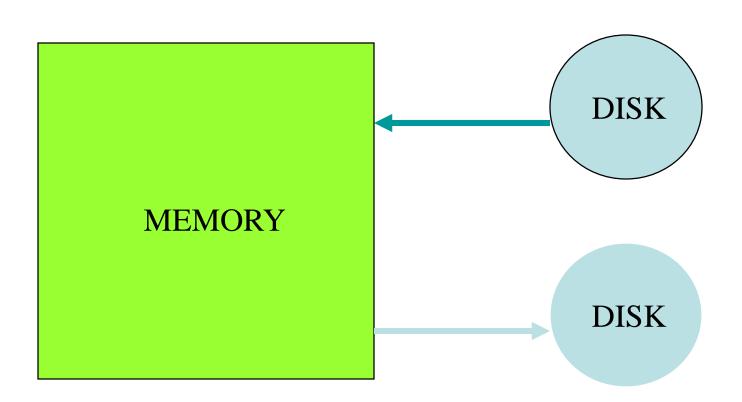

= (200t_{IO} + 100t_{IM}) * 5
```

Factors In Overall Run Time

- Run generation. 200t_{IO} + 20t_{IS}
 - Internal sort time.
 - Input and output time.
- Run merging. $(200t_{IO} + 100t_{IM})$ * ceil(log₂(20))
 - Internal merge time.
 - Input and output time.
 - Number of initial runs.
 - Merge order (number of merge passes is determined by number of runs and merge order)

Improve Run Generation

Overlap input, output, and internal sorting.

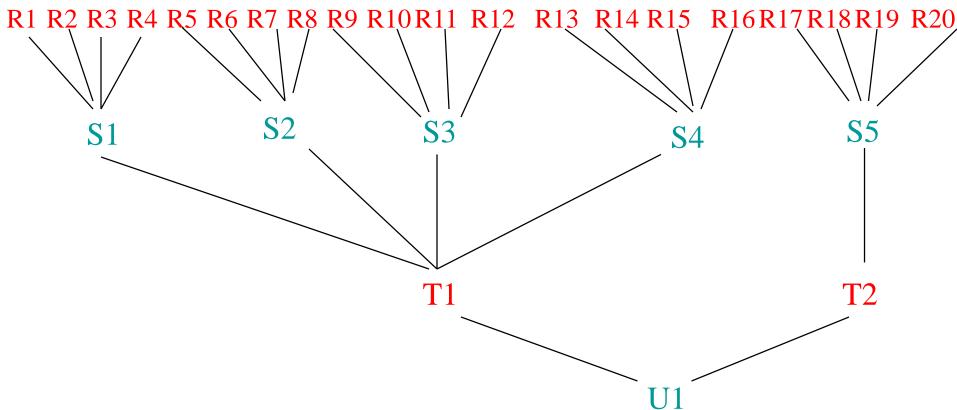

Improve Run Generation

- Generate runs whose length (on average) exceeds memory size.
- Equivalent to reducing number of runs generated.

Improve Run Merging

- Reduce number of merge passes.
 - Use higher-order merge.
 - Number of passes
 = ceil(log_k(number of initial runs))
 where k is the merge order.

Merge 20 Runs Using 4-Way Merging

Number of merging passes = 3

Total passes = 1 (run generation) + 3 (mering) = 4_{44}

Time For Pass 1 (R→ S)

- Time to merge 4-way of runs $40t_{IO} + 20t_{IM}$.
- Time to merge all runs (5 blocks/run)
 200t_{IO} + 100t_{IM}.

Total Run-Merging Time

 (time for one merge pass) * (number of passes)

```
= (time for one merge pass)

* ceil(log<sub>4</sub>(number of initial runs))

= (200t_{IO} + 100t_{IM}) * ceil(log<sub>4</sub>(20))

= (200t_{IO} + 100t_{IM}) * 3
```

Run Generation

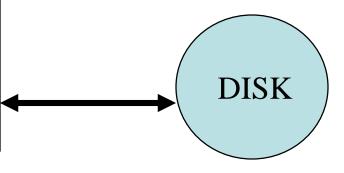

MEMORY

500 records

83 records/block

6 blocks

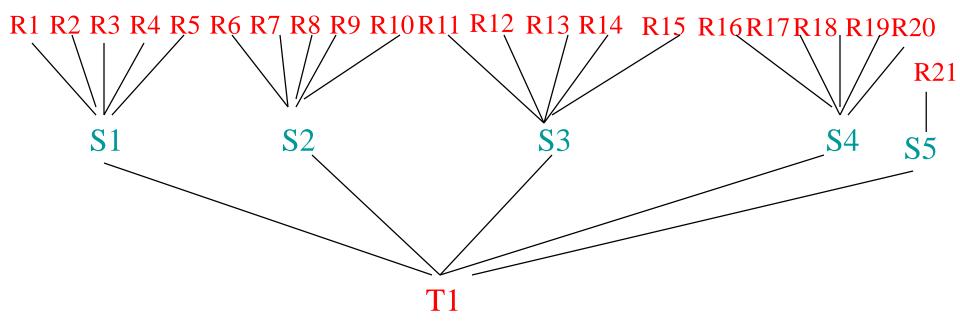

10,000 records 83 records/ block 121 blocks

- Input 6 blocks.
- Sort.
- Output 6 blocks as a run.
- Do 21 times.

- 6 t₁₀
- t_{IS}
- 6 t_{IO}
- $242t_{IO} + 21t_{IS}$

Merge 21 Runs Using 5-Way Merging

Number of merging passes = 2

Total passes = 1 (run generation)+2 (merging)

Time For Pass 1 $(R \rightarrow S)$

- Time to merge 5-way of runs
 60t_{IO} + 30t_{IM}.
- Time to merge all runs (6 blocks/run)
 242t_{IO} + 121t_{IM}.

Total Run-Merging Time

 (time for one merge pass) * (number of passes)

```
= (time for one merge pass)

* ceil(log<sub>5</sub>(number of initial runs))

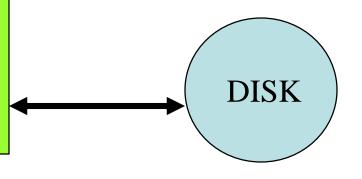

= (242t_{IO} + 121t_{IM}) * ceil(log<sub>5</sub>(21))

= (242t_{IO} + 121t_{IM}) * 2
```

Run Generation

MEMORY
500 records
10 blocks

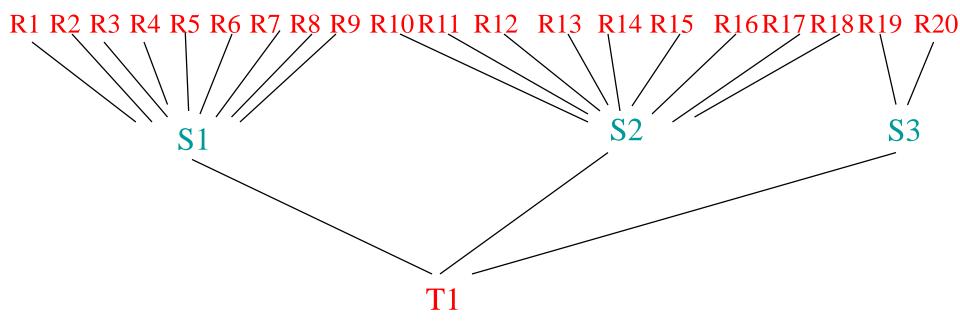

10,000 records
200 blocks
50 records/ blocks

- Input 10 blocks.
- Sort.
- Output 10 blocks as a run.
- Do 20 times.

- 10 t_{IO}
- t_{IS}
- 10 t_{IO}
- $400t_{IO} + 20t_{IS}$

Merge 20 Runs Using 9-Way Merging

Number of merging passes = 2

Total passes = 1 (run generation)+2 (merging)

Time For Pass 1 $(R \rightarrow S)$

- Time to merge 9-way of runs $180t_{IO} + 90t_{IM}$.
- Time to merge all runs $800t_{IO} + 400t_{IM}$.

Total Run-Merging Time

 (time for one merge pass) * (number of passes)

```
= (time for one merge pass)

* ceil(log<sub>2</sub>(number of initial runs))

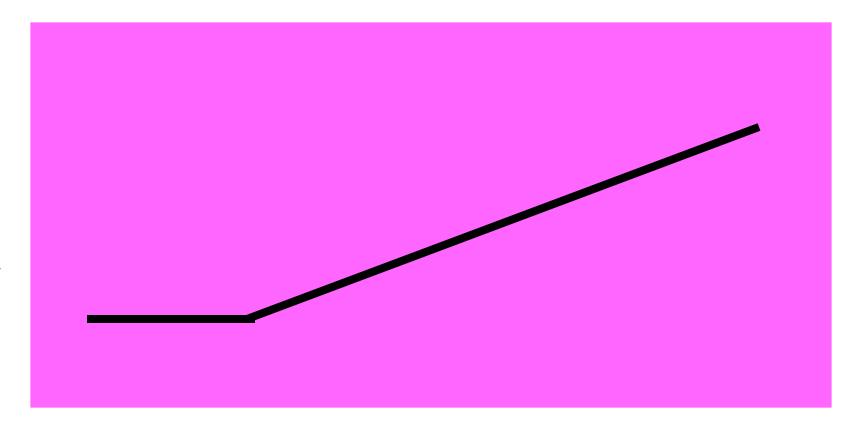

= (400t_{IO} + 200t_{IM}) * ceil(log<sub>9</sub>(20))

= (400t_{IO} + 200t_{IM}) * 2
```

I/O Time Per Merge Pass

- Number of input buffers needed is linear in merge order k.
- Since memory size is fixed, block size decreases as k increases (after a certain k).
- So, number of blocks increases.
- So, number of seek and latency delays per pass increases.

I/O Time Per Merge Pass

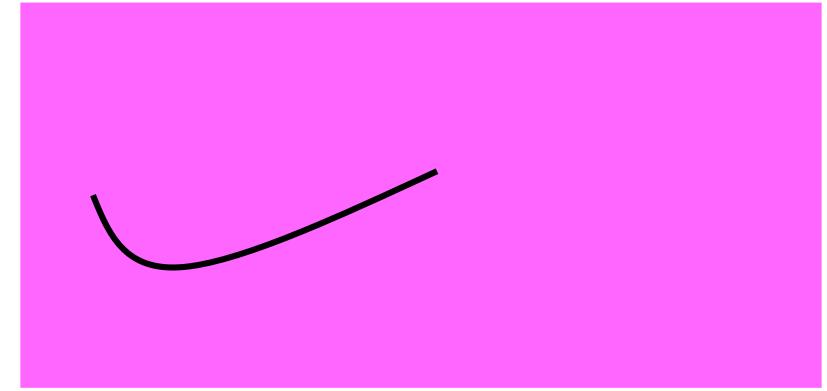

I/O time per pass

k 56

Total I/O Time To Merge Runs

(I/O time for one merge pass)
 * ceil(log_k(number of initial runs))

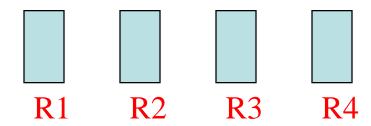

Total I/O time to merge runs

57

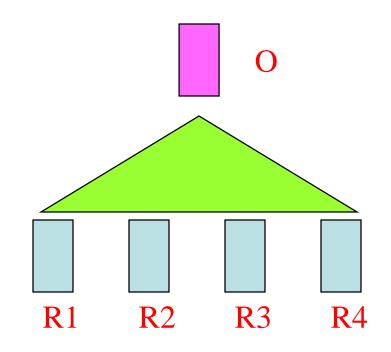

Internal Merge Time

- Naïve way=> k 1 compares to determine next record to move to the output buffer.
- Time to merge n records is c(k 1)n, where c is a constant.
- Merge time per pass is c(k 1)n.
- Total merge time is c(k 1)nlog_kr.

Merge Time Using A Selection Tree

- Time to merge n records is dnlog₂k, where d is a constant.
- Merge time per pass is dnlog₂k.
- Total merge time is (dnlog₂k) log_kr = dnlog₂r.

59

Improve Run Merging

- Reduce number of merge passes.
 - Use higher order merge.
 - Number of passes
 - = ceil(log_k(number of initial runs)) where k is the merge order.
- More generally, a higher-order merge reduces the cost of the optimal merge tree.
